A dissertation submitted to the University of Cambridge  
for the degree of Doctor of Philosophy

## Abstract

This thesis describes the optimisation of the calorimeter design for collider experiments at the future Compact Linear Collider (CLIC) and the International Linear Collider (ILC). The detector design of these experiments is built around high-granularity Particle Flow Calorimetry that, in contrast to traditional calorimetry, uses the energy measurements for charged particles from the tracking detectors. This can only be realised if calorimetric energy deposits from charged particles can be separated from those of neutral particles. This is made possible with fine granularity calorimeters and sophisticated pattern recognition software, which is provided by the PandoraPFA algorithm. This thesis presents results on Particle Flow calorimetry performance for a number of detector configurations. To obtain these results a new calibration procedure was developed and applied to the detector simulation and reconstruction to ensure optimal performance was achieved for each detector configuration considered.

This thesis also describes the development of a software compensation technique that vastly improves the intrinsic energy resolution of a Particle Flow Calorimetry detector. This technique is implemented within the PandoraPFA framework and demonstrates the gains that can be made by fully exploiting the information provided by the fine granularity calorimeters envisaged at a future linear collider.

A study of the sensitivity of the CLIC experiment to anomalous gauge couplings that effect vector boson scattering processes is presented. These anomalous couplings provide insight into possible beyond standard model physics. This study, which utilises the excellent jet energy resolution from Particle Flow Calorimetry, was performed at centre-of-mass energies of 1.4 TeV and 3 TeV with integrated lumi-

nosities of  $1.5\text{ab}^{-1}$  and  $2\text{ab}^{-1}$  respectively. The precision achievable at CLIC is shown to be approximately one to two orders of magnitude better than that currently offered by the LHC.

Finally, a study into various technology options for the CLIC vertex detector is described.

## Declaration

This dissertation is the result of my own work, except where explicit reference is made to the work of others, and has not been submitted for another qualification to this or any other university. This dissertation does not exceed the word limit for the respective Degree Committee.

Andy Buckley

## Acknowledgements

Of the many people who deserve thanks, some are particularly prominent, such as my supervisor...

## Preface

This thesis describes my research on various aspects of the LHCb particle physics program, centred around the LHCb detector and LHC accelerator at CERN in Geneva.

For this example, I'll just mention Chapter ?? and Chapter ??.

### 1.1 Physics Theory

Quantum field theory is the best model that currently exists for the behaviour of fundamental particles in the universe. It is based upon fundamental symmetries that are obeyed by the Lagrangian, which dictates how particles behave. The standard model is a non-abelian gauge theory of the  $SU(3) \times SU(2)_L \times U(1)$  symmetry. This symmetry acts to describe the electromagnetic, weak nuclear and strong nuclear forces observed in the universe. This occurs via force mediating boson particles, 12 gauge bosons in total, 1 photon, 3 weak bosons and 8 gluons.

The gauge symmetry forbids a mass term for any of these bosons, however, the electroweak gauge bosons have been measured to be massive indicating a piece is missing from this theory. This problem is solved via the introduction of the Higgs field that undergoes spontaneous symmetry breaking.

#### 1.1.1 Spontaneous Symmetry Breaking

To begin with consider a complex scalar field  $\phi$  with the Klein-Gordon Lagrangian

$$\mathcal{L} = \partial^\mu \phi^* \partial_\mu \phi - m^2 |\phi|^2 = \partial^\mu \phi^* \partial_\mu \phi - V(\phi) \quad (1.1)$$

$\partial^\mu$  is the partial derivate of the scalar field  $\phi$  with respect to the position 4-vector.  $\mathcal{L}$  is Lorentz invariant.

This Lagrangian is invariant under the global symmetry  $\phi \rightarrow e^{i\alpha} \phi$ . By adding extra terms to the Lagrangian that retain the invariance to the global symmetry it is possible to modify interactions of this scalar field. This can be interpreted as modifying the potential, all terms in the Lagrangian without derivatives, of the scalar field. For example consider a fourth order potential of the following form.

$$V(\phi) = m^2 |\phi|^2 + \lambda |\phi|^4 \quad (1.2)$$

The potential has a minima at zero, however, if  $m^2 < 0$  then the minima exists on a circle in the complex  $\phi$  plane. This complex circle is centred at  $(0,0)$  and has radius  $\sqrt{\frac{-m^2}{\lambda}}$ . To quantise this theory it is necessary to expand about the minima of the potential, however, in the case of  $m^2 < 0$  there are an infinite number of choices of minima to expand about. Irrespective of the choice of minima for this configuration the symmetry  $\phi \rightarrow e^{i\alpha} \phi$  is broken. Fluctuations about the minima along the degenerate direction leave the potential unchanged, which is a consequence of the breaking of the  $\phi \rightarrow e^{i\alpha} \phi$  symmetry; this is known as spontaneous symmetry breaking.

Goldstone's theorem implies that for Lorentz-invariant theories spontaneous symmetry breaking always leads to the existence a massless particle and this can be seen when expanding the complex scalar theory example about the minima.

$$\phi = \frac{1}{\sqrt{2}}(v + \phi_1 + i\phi_2) \quad (1.3)$$

Where  $\phi_{1/2}$  are real fields. Applying this parameterisation to the Lagrangian shows yields a mass term of  $\sqrt{-m^2}$  for the  $\phi_1$  field while the mass of the  $\phi_2$  field yields a massless particle.

$$\mathcal{L} = \frac{1}{2}\partial^\mu\phi_1\partial_\mu\phi_1 + \frac{1}{2}\partial^\mu\phi_2\partial_\mu\phi_2 - m^2|\phi_1|^2 + 0\cdot|\phi_2|^2 + \dots \quad (1.4)$$

This procedure is the origin of the gauge boson mass terms when considering local symmetries instead of global ones. This can be seen in the example under consideration by promoting the global to local symmetry let  $\alpha \rightarrow \alpha(x)$  and  $\partial^\mu \rightarrow D^\mu = \partial^\mu + ieA^\mu$  where  $A^\mu$  is the gauge field that transforms as  $A^\mu \rightarrow A^\mu - \partial^\mu\alpha(x)$ . The new Lagrangian becomes

$$\mathcal{L} = (D^\mu\phi)^*(D_\mu\phi) - m^2|\phi|^2 - \lambda|\phi|^4 \quad (1.5)$$

If there is a non zero minima in the potential,  $v$ , then a gauge boson mass term appears of the form  $+\frac{e^2v^2}{2}A^\mu A_\mu$ .

### 1.1.2 Electroweak Interactions

The electroweak sector of the standard model is that related to the  $SU(2)_L \times U(1)$  symmetry. In this sector spontaneous symmetry breaking must occur in such a way as to leave three massive gauge bosons,  $W^\pm$  and  $Z$ , and one massless gauge boson, the photon. This can be achieved by considering a Higgs field  $H$  that is a doublet of the  $SU(2)_L$  symmetry, with weak hypercharge  $\frac{1}{2}$ , in the following potential.

$$V(\phi) = -\mu^2 H^\dagger H + \lambda(H^\dagger H)^2 \quad (1.6)$$

The minima of this field is at

$$\sqrt{H^\dagger H} = \frac{v}{\sqrt{2}} = \sqrt{\frac{\mu^2}{2\lambda}} \quad (1.7)$$

without loss of generality we may choose to expand this field around the point

$$\langle H \rangle = \begin{pmatrix} 0 \\ \frac{v}{\sqrt{2}} \end{pmatrix} \quad (1.8)$$

where  $v$  is real. Consider the kinematic term in the Lagrangian,  $\partial^\mu H^\dagger \partial_\mu H$ . The covariant derivative of this Higgs field must satisfy the  $SU(2)_L \times U(1)$  gauge symmetry and so takes the form

$$D_\mu H = (\partial_\mu + ig \frac{\sigma^i}{2} W_\mu^i + i \frac{g'}{2} B_\mu) H \quad (1.9)$$

If there is mixing of the  $SU(2)_L$  and  $U(1)$  fields of the form  $W_\mu^3 = \cos\theta_W Z_\mu + \sin\theta_W Z_\mu$  and  $B_\mu = -\sin\theta_W Z_\mu + \cos\theta_W Z_\mu$  and the unmixed  $SU(2)_L$  fields transform in the following way  $W_\mu^\pm = \frac{1}{\sqrt{2}}(W_\mu^1 \mp iW_\mu^2)$ , then non zero mass terms for the electroweak bosons arise.  $\theta_W$  is known as the Weinberg angle.

$$\frac{(gv)^2}{4} W_\mu^+ W^{-\mu} + \frac{(g^2 + g'^2)v^2}{8} Z_\mu Z^\mu \quad (1.10)$$

The boson mass terms are as follows

$$m_W = \frac{gv}{2}, m_Z = \frac{v\sqrt{g^2 + g'^2}}{2} = \frac{m_W}{\cos\theta_W}, m_A = 0 \quad (1.11)$$

This model yields a massless photon,  $m_A = 0$ , as well as producing massive electroweak gauge bosons in a ratio that match the measured values of  $m_W = 80.385 \pm 0.015$  and  $m_Z = 91.1876 \pm 0.0021$  [1]. These masses predicate that  $\rho = 1$  where  $\rho$  is defined as:

$$\rho = \frac{m_W^2}{m_Z^2 \cos^2\theta_W} \quad (1.12)$$

This ratio is constant, which occurs due to the custodial symmetry that exists after the  $SU(2)_L \times U(1)$  symmetry has been broken to  $U_Q(1)$ .

### 1.1.3 Effective Field Theory

There are a number of features in the observable universe that cannot be accounted for using the standard model of particle physics. However, the standard model is a very good description of the interactions between particles over the energy range being probed at modern particle collider experiments. Therefore, any underlying theory governing the interactions of particles must behave like the standard model over the energy range, or distance scale, that modern particle collider experiments have covered and above this will deviate to account for the true underlying theory. Effective field theories (EFTs) work from this premise by assuming that an underlying theory has a momentum scale,  $\Lambda$ , below which standard model behaviour is replicated.

Quantum field theories must be renormalizable to ensure that non-infinite predictions of the coefficients in the Lagrangian can be made and tested. Infinities arise from non-renormalizable theories due to divergent integrals from loop diagrams that assume the theory being applied is valid at all energy and length scales. Effective field theories act to avoid such problems by only integrating up to the momentum (mass) scale  $\Lambda$  ( $\Delta$ ) and not above it. At the energy scale being considered for the EFT any infinities arising from the loop calculations can be absorbed into a finite number of parameters. This methodology avoids the assumption that the theory in question is applicable to all energy scales and allows measurable predictions to be made.

In the EFT framework it is no longer necessary to enforce renormalization in the choice of operators appearing in the Lagrangian. As the standard model should be replicated at the low energy scale it is appropriate when creating the EFT Lagrangian to append new operators to the standard model Lagrangian, which account for new physics. These new terms do not necessarily have to obey the same gauge symmetries of the standard model, but can contain a variety of new terms. The general form for an EFT Lagrangian is:

$$\mathcal{L}_{EFT} = \mathcal{L}_{SM} + \sum_{\text{dimension } d} \sum_i \frac{c_i^{(d)}}{\Lambda^{d-4}} \mathcal{O}_i^{(d)} \quad (1.13)$$

where  $c_i^{(d)}$  are the coefficient of the operators  $\mathcal{O}_i^{(d)}$  and the summations run over all the dimensions,  $d$ , of the operator and all unique operators,  $i$ , of dimension,  $d$ . The presence of the  $\Lambda^{d-4}$  in the denominator is needed to ensure correct dimensionality of the new terms being added to the Lagrangian, but it also sets the scale of new physics being modelled,  $\Lambda$ . At energies below this scale it is possible to find the dominant terms for the EFT and consider these as corrections to the standard model, while above this scale the EFT breaks down as each term in the Lagrangian has a non-negligible coefficient. In the extremal limit,  $\Lambda \rightarrow \infty$ , the standard model is recovered as new physics is too far out of reach to have any impact on observables.

#### 1.1.4 Electroweak Chiral Lagrangian

While the introduction of a Higgs field transforming appropriately under the relevant gauge transformations is able to produce mass terms in the Lagrangian for the  $W^\pm$  and  $Z$  bosons it is possible to introduce these terms via an effective field theory approach. In this approach the effective field theory considered is that of the electroweak chiral Lagrangian, which takes the place of the Higgs field in the standard model.

In this model the symmetry breaking is achieved by introducing a field  $\Sigma(x)$  that transforms under the  $SU(2)_L$  transformations  $U(x)$  and  $U(1)$  transformations  $V(x)$  as

$$\Sigma(x) \rightarrow U(x)\Sigma(x)V^\dagger(x) \quad (1.14)$$

$\Sigma(x)$  is parameterised as follows

$$\Sigma(x) = \exp\left(\frac{-i}{v}\Sigma_{a=1}^3 w^a \tau^a\right) \quad (1.15)$$

where  $w^a$  are the Goldstone bosons generated from the spontaneous symmetry breaking of the electroweak symmetry. The following term if added to the Lagrangian generate the mass terms for the  $W^\pm$  and  $Z$  gauge bosons.

$$\mathcal{L}_M = \frac{v^2}{4} \text{Tr}(\mathcal{D}^\mu \Sigma^\dagger \mathcal{D}_\mu \Sigma) = -\frac{v^2}{4} \text{Tr}(V_\mu V^\mu) \quad (1.16)$$

Where  $V_\mu = (\mathcal{D}_\mu \Sigma) \Sigma^\dagger$  and  $m_W = \frac{gv}{2}$ . The covariant derivate of the  $\Sigma(x)$  is defined as

$$\mathcal{D}_\mu \Sigma(x) = \partial_\mu \Sigma(x) + \frac{ig}{2} W_\mu^a \tau^a \Sigma(x) - \frac{ig'}{2} B_\mu \tau^3 \Sigma(x) \quad (1.17)$$

This term yields the following mass terms for the gauge bosons, which match those expected from the introduction of a Higgs field as was done in section 1.1.1.

$$\frac{v^2}{4} \text{Tr}[V^\mu V_\mu] = -\frac{(gv)^2}{4} W_\mu^+ W^{-\mu} - \frac{(g^2 + g'^2)v^2}{8} Z_\mu Z^\mu \quad (1.18)$$

$$m_W = \frac{gv}{2}, m_Z = \frac{v\sqrt{g^2 + g'^2}}{2} = \frac{m_W}{\cos\theta_W} \quad (1.19)$$

The full parameterisation of the gauge boson interactions is found in [3]. It is sufficient to note that the origin of these terms is the parameterisation of the Higgs field through  $\Sigma$  that replicates the low energy behaviour of the standard model. It was shown by Longhitano that there are several relevant operators that are  $SU(2)_L \times U(1)$  and CP invariant up to dimension 4 that should be considered in this theory [4]. Of those operators only two involve quartic massive gauge boson vertices. They are:

$$\alpha_4 \text{Tr}[V^\mu V_\mu] \text{Tr}[V^\nu V_\nu] \text{ and } \alpha_5 \text{Tr}[V^\mu V_\mu]^2 \quad (1.20)$$

The full expansion of these terms in terms of the massive gauge bosons  $W^\pm$  and  $Z$  is given in the appendices ???. These terms contribute to the vector boson scattering

processes involving  $W^\pm$  and  $Z$  bosons. A study into the sensitivity of the CLIC experiment to the anomalous gauge couplings  $\alpha_4$  and  $\alpha_5$  is presented in section ??.
